Conclusion

# Identifying an information state is a key step in centralized dynamic programming

## Properties of information state

- ▶  $\pi_t$  is a function of the information  $I_t$
- ▶  $\pi_{t+1}$  is a function of  $\pi_t$  and new information  $(u_t, y_{t+1})$
- ▶  $\pi_t$  is a sufficient statistic for predicting future observations

$$\mathcal{P}(y_{t+1} \mid I_t) = \mathcal{P}(y_{t+1} \mid \pi_t)$$

- ▶  $\pi_t$  is sufficient for performance evaluation

$$\mathcal{E}[c(x_t, u_t) \mid I_t, u_t] = \mathcal{E}[c(x_t, u_t) \mid \pi_t, u_t]$$

## Examples of information states

- ▶ In partially observable Markov decision problems (POMDPs), the belief state  $\mathcal{P}(x_t \mid I_t)$  is an information state.
- ▶ In linear quadratic and Gaussain (LQG) problems, the state estimate  $\hat{x}_{t|t}$  is an information state.

DP uses the information state to **sequentially decompose** the optimization problem

### Structural result

Restricting attention to control laws of the form  $u_t = \gamma_t(\pi_t)$  does not entail any loss of optimality.

- ▶ In some cases, also derive qualitative properties of the optimal policy (monotonicity, convexity, threshold, etc.)

# DP uses the information state to **sequentially decompose** the optimization problem

## Structural result

Restricting attention to control laws of the form  $u_t = \gamma_t(\pi_t)$  does not entail any loss of optimality.

- ▶ In some cases, also derive qualitative properties of the optimal policy (monotonicity, convexity, threshold, etc.)

## Dynamic programming decomposition

Recursively define

$$V_t(\pi_t) = \inf_{u_t \in \mathbb{U}_t} \mathcal{E} [c(x_t, u_t) + V_{t+1}(\pi_{t+1}) \mid \pi_t, u_t]$$

If the infimum is achieved, then the arg min at time  $t$  gives the optimal control action at information state  $\pi_t$ .

- ▶ Functional vs parameteric optimization
